Abstract. Mass increase of vinylchloride-maleic anhydride (VC-MA) copolymer samples aged in tetrahydrofuran (THF) or in 1,4-dioxane results from chemical interaction of VC-MA macromolecules with 1,4-dioxane or THF. Microstructure of the products of such modification was proved by infrared spectroscopy (IR-) and nuclear magnetic resonance spectroscopy ($^{13}$C NMR and $^1$H NMR). Mechanism of modification has been proposed. The results of microstructure research of VC-MA samples aged in THF and in 1,4-dioxane coincide with already known data on the reactions of opening of these and other oxygen-containing cycles under mild conditions.

Keywords: polymer synthesis, molecular engineering, graft copolymers, vinyl chloride-maleic anhydride copolymers, tetrahydrofuran, 1,4-dioxane

1. Introduction

Alternating, statistical and graft copolymers of maleic anhydride (MA) exhibit quite a number of valuable properties. Thus MA and vinyl chloride (VC) copolymers easily enter into various reactions and are considered as convenient initial products for polymer synthesis of new substances utilized as biologically active materials and enzyme carriers, ionites, photographic, pharmaceutical, pore-forming, antifriction materials etc [1]. Copolymers of vinyl monomers with MA are applied in automotive industry [2] and they are also used as the initial reagents to produce novel composite materials. Sodium salts of succinic anhydride derivatives are widely used as dispersants, flocculants and soil modifiers [3]. Biomedical application of the MA copolymers as medicines and their carriers is also of interest.

The VC-MA copolymer easily reacts with water and alcohols [4, 5], sodium azide [6], carbonyl-containing solvents and dimethyl sulfoxide [7]. In deuterated acetone medium deuteroexchange was detected in the enol fragments of the macromolecules [8]. The reactions of the VC-MA copolymers with dimethyl formamide molecules proceed as regiospecific to form long-living solvate structures [9].

The present work is aimed at studying chemical modification of the VC-MA copolymer with such cyclic ethers as THF and 1,4-dioxane as a mode of molecular engineering.

2. Experimental

The samples of VC-MA copolymer were obtained by radical copolymerization of MA and VC at 80°C for 24 h in sealed tubes in 1,2-dichlorethane with benzoyl peroxide (1 mass%) and with a comonomer ratio of 1:1 [10]. The initial reagents and solvents were thoroughly refined [11]. The IR
spectra were recorded on a FTIR-Spectrometer Nicolet 5700 (Thermo Electron, USA) in tablets with KBr (2 mg/300 mg KBr); 1H and 13C NMR spectra – on a Bruker Avance AV 300 NMR Spectrometer (Bruker, Germany) with operating frequency 300 and 75 MHz accordingly at 25°C in d6-acetone (10 mass% solutions), where acetone was used as an internal standard. All experiments were carried out under conditions excluding any contact with atmospheric moisture to prevent hydrolysis of the succinic anhydride rings.

The process of grafting of THF and 1,4-dioxane was carried out in tightly closed flasks (0.5 g of VC-MA and 4 ml of the solvent). In a day homogeneous viscous solutions were carefully carried into the preliminary weighted Petri dishes and left for a week to remove the solvents. The formed films were dried in vacuo to constant mass. The mass of the aged samples increased by 8–10 mass% as compared to the mass of the initial VC-MA copolymer. Calculation of grafting efficiency: degree of polymerization is ca 600; 30 mol% (initial) of repeated units are tautomerized in the enol forms (see below) [12, 13]. If all enol forms had been involved in grafting the mass increase of the sample treated by THF would have been 12 mass%. The 8–10 mass% increase indicates that 60 mol% of the initial enol forms participate in grafting.

3. Results and discussion

Due to the action of different catalysts (HCl, (CH3CO)2O, (POCl 3 + H2SO4) and H3PO4) THF cycles open under mild conditions [14, 15]. As an example THF cycle opening in the presence of R3O·BF4 is accompanied by polymerization (Figure 1). The other reactions of oxygen-containing cycle polymerization are also known [16].

Marked increase in the VC-MA copolymer mass after its aging in THF and in 1,4-dioxane media was unexpected. To explain this fact we supposed that certain tautomeric forms of the repeated units of VC-MA copolymer [10] interact with solvent molecules, which open with simultaneous grafting on them.

In the solvents of various nature VC-MA copolymer undergoes cycloanhydride-enol tautomerism resulting in dynamic micro structural heterogeneity in the form of enol Δ6en (see b, d, f and h in Figure 2) and dienol derivatives of furan being tautomers of jointly VC and MA comonomer units, which afterwards appear in the macromolecular chains as succinic anhydride derivatives [10, 17]. Formation of Δ6en tautomer forms is accompanied by appearance of aromatic carbon atom signals in the 13C NMR spectrum of the VC-MA cycles.
sample in the region of 124–146 ppm (Figure 3) [18]. Under the selected synthesis conditions macromolecules of equimolar VC-MA copolymer were earlier found [12] to consist of the statistical sequence of the VC-MA repeat units (~67 mol%) and their $\Delta^6$en tautomers (~33 mol%) (Figure 2) which was proved by mathematical modeling of the microstructure of the macromolecules in view [13]. It was suggested just the [Cl…H–O–C$^\delta^+$]# ensembles (Figure 2) that are the reaction centers causing cycle opening. Their high-energy transition state promotes formation of oxonium ions causing breakage of THF and 1,4-dioxane cycles: Figure 4 presents a mechanism of THF cycles grafting on the macromolecules of the VC-MA copolymer. As a result of nucleophilic attack at the C–Cl carbon atom (a) an oxonium compound is being formed (b) with simultaneous bonding breakage of the intramolecular hydrogen bond and hydrogen migration to its original position (c), THF cycle being opened at the same time (d).

To determine microstructure of VC-MA macromolecules modified with THF we used IR-, $^{13}$C and $^1$H NMR-spectroscopy. The IR spectrum of VC-MA aged in THF exhibits new bands: $\nu$–C–O–C– (1174 cm$^{-1}$), $\nu$CH$_2$ (2588 and 2893 cm$^{-1}$), $\delta$CH$_2$ (1368 cm$^{-1}$) and $\delta$CH (876 and 835 cm$^{-1}$), and the band intensity of $\delta$CH$_2$ (1440 cm$^{-1}$) highly increases (see 1, 2 in Figure 5). The substantial change in the C–Cl carbon environment (Figures 4a and 4d) leads to the increased intensity of the $\nu$CCl absorption band (619 cm$^{-1}$). Besides one observes redistribu-

**Figure 4.** Mechanism of THF cycles grafting on the VC-MA macromolecules
tion of band intensities at 1863, 1789 and 1716 cm\(^{-1}\) caused by \(\nu_{C=O}\) of the succinic anhydride ring.

The \(^1\)H NMR spectrum of the same VC-MA sample exhibits multiplets at 3.6–3.7 and 1.7–1.8 ppm (Figure 6b; unequivalent methylene groups of the attached THF molecules \(\text{Cl–CH}_2\text{-CH}_2\text{-CH}_2\text{-CH}_2\text{-O–}) absent in the spectrum of the initial VC-MA sample (Figure 6a). In the \(^{13}\)C NMR spectrum two additional signals at 26 and 68 ppm of unequivalent \(\text{CH}_2\) carbons are registered (Figure 7a).

If polymerization which is accompanied by THF cycles opening is well investigated, the six-member cycles of 1,4-dioxane are known to form peroxides rather easily [19], but they do not undergo polymerization [15]. After aging of the VC-MA samples in the freshly refined 1,4-dioxane its mass substantially increases. A probable mechanism of 1,4-dioxane interaction with \(\Delta^6\text{en}\) reaction centers is presented in Figure 8.

The changes in the region of 4000–1500 cm\(^{-1}\) in the IR spectrum of VC-MA aged in 1,4-dioxane (see 3 in Figure 5) are identical to the above described changes observed in the IR spectrum of the VC-MA aged in THF. Besides new absorption

**Figure 5.** The IR spectra of the original VC-MA sample (1), of the VC-MA sample aged in THF (2) and of the VC-MA sample aged in 1,4-dioxane (3)

**Figure 6.** The \(^1\)H NMR spectra the original VC-MA sample (a), of the VC-MA sample aged in THF (b) and of the VC-MA sample aged in 1,4-dioxane (c)
bands ν_C–O–C_ (1117 cm–1) and δ_CH (868 and 826 cm–1) appear. Absorption bands of δ_CH2 (1375 cm–1) and ν_CCl (614 cm–1) become more pronounced. The intensity of the δ_CH2 absorption band (1445 cm–1) increases.

The 1H NMR spectrum of the VC-MA sample aged in 1,4-dioxane has an intensive multiplet at 3.5–3.7 ppm referred to the equivalent CH2 protons of the dioxane fragments attached (Figure 6c). A new signal at 67.5 ppm of CH2 carbon of the same fragments was registered in the 13C NMR spectrum of the same sample (Figure 7b).

4. Conclusions

Thus reactive Δ^6 en tautomeric forms of the repeat units of the VC-MA copolymer react with THF and 1,4-dioxane molecules to form short chain graft copolymers. In other words, the high energy transition state of the ensembles [Cl…H–O–C_δ+]# appear to play the role of catalytic sites in situ. On an average ca 60 mol% of the Δ^6 en tautomeric forms of macromolecules is involved in grafting.
